Changes in FARM PRODUCTION AND EFFICIENCY

1956 SUMMARY

U. S. DEPARTMENT OF AGRICULTURE
Agricultural Research Service
WASHINGTON, D. C August 1957

ARS 43-55

PREFACE

This is the fourth issue of an annual publication that was designed specifically to present the major statistical series on farm production, production inputs, and efficiency. The publication was inaugurated as a means of providing in one place the latest information for each of the several series that have been developed to appraise such things as production in peace and war, changes in farm inputs and practices, improvement in labor productivity, and progress of farm mechanization.

The many people who are interested in keeping abreast of, or making studies of, changes in the output and productive efficiency of agriculture in the United States will find the information contained herein of use. The data will help the user to get a historical perspective of what has happened and to measure current changes.

Although the publication consists basically of statistical series, a brief digest of what each series shows to date is included, as is an explanation of the methods used in developing each statistical measure.

Many of the tables in this issue contain revised data for the years 1950 to date and in some instances for previous years. These revisions resulted primarily from the release of enumerated date from the 1954 Census of Agriculture taken by the Bureau of the Census, U. S. Department of Commerce.

For several of the series, data are presented for geographic divisions as well as for the United States as a whole. Data for geographic divisions are available for some of the other series shown here on a national basis. These data are issued as supplements which are available upon request.

Supplement I contains nine regional tables of index numbers of farm production for each of the groups of livestock and crops shown in table 1.

Supplement II contains nine regional tables of index numbers of man-hours of farm labor used for each of the groups of livestock and crops shown in table 13.

Supplement III contains nine regional tables of index numbers of farm production per man-hour for each of the groups of livestock and crops shown in table 15.

Requests for these supplements should be sent to the Information Division, Agricultural Research Service, United States Department of Agriculture, Washington 25, D. C.

Several persons in the Farm Income Branch and the Agricultural Estimates Division, Agricultural Marketing Service, assisted by supplying the data on which many of the series are based.

LIST OF TABLES

CHANGES IN FARM PRODUCTION AND EFFICIENCY
1956 Summary

HIGHLIGHTS OF CHANGES

Farm output and production, by groups of commodities. - United States farm output for 1956 was at a record high. It was 1 percent above the previous high set in 1955 and 13 percent greater than the average 1947-49 outturn (table 1). This achievement in 1956 was due to a record output of livestock and livestock products combined with a crop output equal to the record of 1948.

The record production of livestock and livestock products in 1956 was about 2 percent greater than in 1955 and 22 percent greater than the average 1947-49 production. Meat animals made up the only livestock group for which production decreased from 1955 to 1956. This was chiefly because of a 6-percent decrease in production of hogs. Dairy products attained a new alltime high in 1956, exceeding the previous record of 1955 by 2 percent, despite a continued decline in the number of milk cows on farms. The poultry and egg group made the greatest increase percentagewise; production increased by more than 10 percent. Production of farm chickens from 1955 to 1956 was up 3 percent, production of commercial broilers 28 percent, and production of eggs 3 percent.

Total crop production in 1956 equaled the peak production of 1948 and was 1 percent greater than the 1955 production. Last year's large crop outturn was attained on a smaller number of acres than in 1955, but production per acre was at an alltime high. Soybeans was the only crop to have a record production. The output of important crops such as corn, winter wheat, spring wheat, flaxseed. and potatoes was greater than in 1955. Total outturn decreased in the cotton, tobacco, feed grains, and the hay and forage crop groups. These reductions were more than offset by gains in the other crop groups.

Farm output by geographic divisions. - Farm output in 1956 was at a record high in the Middle Atlantic, East North Central, South Atlantic, and Pacific geographic divisions (table 2). The New England and West South Central divisions were the only divisions in which farm output was less than the average in 1947-49. The other divisions had near-record outturns.

Acreages of harvested crops used for specified purposes. - Of the 326 million acres of harvested crops in 1956, about 16 percent were used to produce products for export; 3 percent produced feed for horses and mules; and 81 percent produced food. fiber, and tobacco for domestic human use. Acreages used for producing commodities exported in 1956 increased substantially from the previous year and were above the 1946-55 average by about 19 percent. Only 9 million acres were needed in 1956 to produce grain and hay for feed for horses and mules on farms and in cities and elsewhere, compared with 92 million acres so used in the World War I period. The 83 million acres thus diverted to production for human use represent nearly a third of the acreage of harvested crops needed to feed our 1956 population of 168 million. We can no longer look to the disappearance of horses and mules as a source of many additional acres for production of agricultural products for human use (table 3).

Cropland used for crops. - Cropland used for crops in 1956 decreased by 1 percent compared with 1955. This was the smallest number of acres since 1947. The acreage of cropland used for crops declined in all divisions, except the Pacific States. Here the acreage returned to the 1952-54 level, 2 percent above 1955. In five geographic divisions, acreage of cropland decreased to the lowest level since 1919 (tables 4 and 5).

Crop production per acre. - Crop production per acre of cropland used was a record in 1956--1 percent above the previous record set in 1955 and 1948. New high yields per acre were attained for corn, spring wheat, barley, potatoes, and tobacco, and the yield of sugar beets equaled the record. Five regions had record or record-equaling crop production per acre. Percentagewise, the East North Central States had the greatest increase per acre in 1956 compared with 1955. The two South Central divisions and the Mountain division had a decline in outturn per acre (tables 4 and 6).

Use of fertilizer and lime. - For the first time in two decades, use of plant nutrients in 1956 did not increase over the previous year (table 7). Apparently on the basis of preliminary data, there may have been a slight decline for the United States as a whole. The West North Central region, in which the rise has been most pronounced in recent years, appears to have contributed most to the overall tendency for fertilizer consumption to level off, or perhaps to decline slightly (tables 8 and 9). The Middle Atlantic States also

showed a decline, though of smaller proportions. Changes in the other regions were minor with all except the New England and South Atlantic regions showing slight increases.

Use of agricultural lime advanced somewhat in 1955 over the recent low point reached in 1954, and preliminary estimates indicate some further gain in 1956 (table 7). However, the present level of use is only about three-fourths that of the 1947-49 average.

Production per breeding unit of livestock. - Animal units of breeding livestock declined 2 percent in 1956 compared with 1955. Production per breeding unit for the United States was a record 4 percent greater than 1955 and 17 percent greater than the 1947-49 average. Milk production per cow in 1956 was above 6,000 pounds for the first time on record. The rate of lay continued an upward trend to 196 eggs per layer, compared with 192 in 1955 (table 10).

Feed per unit of production. - The outstanding feature of the change in feed per unit of production was the rapid increase in feed efficiency for broilers in recent years, compared with milk, cattle, eggs, or hogs (table 11).

Man-hours of farmwork. - The labor input in farming totaled a little more than 14 billion man-hours in 1956. This is lower than for any previous year; it indicates a continuation of the longtime downward trend (table 12). The total for 1956 represents a reduction of almost two-fifths from the pre-World War I average.

Although the annual variation in man-hours of labor used for farmwork was considerable, an average of around 23 billion hours was used per year until about 1930. The poor crops in the drought years of 1934 and 1936 resulted in low labor needs for these years. Mechanization and other factors have been dominant in reducing man-hours of farmwork by almost a third since before World War II and by 17 percent since 1947-49.

The amount of farm labor used by the different crops and livestock has followed various trends through the years (table 13). The labor used in caring for horses and mules has been reduced sharply, chiefly as a result of the decline in numbers of these animals. The longtime increase in time devoted to other kinds of livestock reflects the rise in numbers and production of livestock. In addition, mechanization of livestock chores has been less pronounced than mechanization of crop production. Only about half as much labor time is now used on crops as was used before World War I.

In use of labor on farms, the Pacific region is unique among the geographic divisions. It is the only region in which more labor is now used on farms than was used in 1919-21 (table 14). The increase in the Pacific region of labor-intensive crops has been chiefly responsible. The greatest decline in farm labor input since the years immediately following World War I has occurred in the West South Central States where it has decreased by 54 percent. It has declined by 40 percent or more in the New England, Middle Atlantic, East North Central, and West North Central regions.

Farm labor productivity. - Even though the input of farm labor in the United States has been reduced significantly, total farm production has continued to increase substantially. More production with less work means that farm output per man-hour is now more than twice as great as the pre-World War II average and more than a third higher than in 1947-49 (table 15). The increase in labor productivity in producing crops has greatly exceeded the rise for livestock. More than 3 times as much crop production is now obtained with each hour of work as before World War I. Livestock production per unit of labor input has increased by less than three-fourths during the same period. However, the difference between crops and livestock in the annual rate of gain has been less in the last few years than for earlier periods.

The upward climb in labor productivity has occurred in all parts of the country (table 16). Since 1919-21, the smallest regional increase in farm output per man-hour has been almost 150 percent. Farm output per hour of labor input has more than tripled in the East North Central States, the area with the greatest increase. This improvement has resulted from an increase of 85 percent in production and a decrease of 40 percent in labor input.

Farm machines. - Although the number of farms decreased from April 1950 to November 1954 by about 600,000, numbers of 7 principal machines on farms increased each year during this period (tables 17 and 18). From April 1, 1950, through January 1, 1957, substantial increases continued in numbers of field tractors, motortrucks, grain combines, cornpickers, pick-up balers, and field forage harvesters; in the order listed, the percentage increases were 36, 31, 43, 57, 168, and 196. The number of garden tractors on farms increased by 74 percent during the 7 years. For several years, farms have been well equipped with automobiles and milking machines. The increase in automobile numbers from 1950 to 1957 was only 1.5 percent, and the increase in number of farms having milking machines was only 13 percent.

Persons supported by production of one farmworker. - During 1956, each farmworker in the United States produced enough food, fiber, and tobacco to supply himself and almost 20 other persons (table 19). This was more than 5 times the number of persons supplied with agricultural products by each farmworker in 1820. More than half of this increase in the number of persons supported per worker, or 53 percent, came in the last 15 years of the 136-year period, when the number of persons supported per worker rose from 11.97 in 1941 to 20.85 in 1956. Improved technology, both on and off the farm, has enabled farmers to produce increasing quantities of farm products with a decreasing number of workers. As a result, our increasing population has continued to be well fed and well clothed. At the same time, rural workers were released for industrial employment. In 1956, farmworkers made up less than 5 percent of the total population, compared with 8 percent of the total in 1940 and 25 percent of the total in 1820.

FARM PRODUCTION

Farm output measures the annual volume of farm production available for eventual human use through sales from farms or consumption in farm households.

Three major subgroups are combined in computing farm output:

Production of crops.- Includes the total constant-dollar value of all crop production, regardless of its final disposition. No deductions are made for seed used or quantities fed to livestock. In calculating farm output, the value of production of hay seeds, pasture seeds, and cover-crop seeds, and of feed used by farm horses and mules, is excluded.

Production of livestock and products.- Includes the total constant-dollar value of production of all livestock and livestock products except horses and mules. Livestock production is made up of three components: Constant-dollar value of pasture consumed, other feed consumed, and product added in converting feed and pasture into livestock and livestock products for human use. The livestock indexes are based on the total constant-dollar value of production of livestock and livestock products. In combining production of livestock and crops into total farm output, the value of feed consumed other than pasture is excluded from livestock production to avoid double counting of the production of feed crops included in crop production.

Feed used by farm horses and mules.- Includes the estimated constant-dollar value of feed other than pasture consumed by this class of livestock. The constant-dollar value of this feed is subtracted from the sum of the values of production of crops and of livestock and livestock products in calculating farm output.

Average values per unit of each commodity were used as weights in constructing the indexes. Separate sets of average values were calculated for use as weights in each of the nine census geographic divisions. The quantity data for crops are total production in the crop year. The quantity data for livestock are net live-weight production or the quantity of livestock products for the calendar year. Official reports of the Crop Reporting Board of the Agricultural Marketing Service are the chief sources of data on both production and prices. The most important item of production omitted was production from farm forests. This, plus other minor items omitted probably accounts for less than 5 percent of the total output in recent years. Commodities of little importance were omitted in some regions for the earlier part of the period covered.

Two weight periods were used. Average values per unit for 1935-39 were used as weights for 1939 and prior years. Weighted average values per unit for 1947-49 were used for the period beginning in 1940. The index series for the two subperiods are "spliced" together in 1940 through the use of overlapped calculations for that year.

Annual quantity-price aggregates for the United States were obtained by summing the regional data for 1919 to date. The series was extended back to 1910 on a United States basis only.

The Crop Reporting Board of the Agricultural Marketing Service calculates the preliminary indexes of crop production for the current year based on its monthly forecasts of crop production beginning in July of each year. These preliminary indexes for the current year are prepared only for the United States total, but they are directly comparable with the historical indexes for the United States built up on a regional basis by the Agricultural Research Service.

The output index differs in concept, but not generally in commodity coverage, from the index of marketings and home consumption prepared by the Agricultural Marketing Service. Both indexes reflect long-run changes in farm production for human use. The output index covers production in the year it is produced; changes in farm inventories of livestock are taken into account. The index of marketings and home consumption reflects production only as it enters the marketing system in the form of sales by farmers or as direct consumption in farmers' households, regardless of the year in which it is produced. The marketings-and home-consumption index tends to be higher than the index of farm output in years when farmers sell or consume more than they produce; conversely, it tends to be lower in years when farmers are building up their inventories.

1/ Production of livestock and livestock products for human use, horses and mules excluded.

2/ Includes clipped wool, mohair, and for 1940 to date, honey and beeswax. These items are not included in the separate groups of livestock and products shown.

3/ Cattle and calves, sheep and lambs, and hogs.

4/ Butter, butterfat, wholesale milk, retail milk, and milk consumed on farms.

5/ Chicken eggs, commercial broilers, chickens, and turkeys.

6/ Includes production of hay seeds, pasture seeds and cover-crop seeds, and some miscellaneous crop production not included in separate groups of crops shown. Coverage of production of seed and miscellaneous crops is more complete for 1940 to date than for prior years.

7/ All corn, oats, barley, and sorghum grain.

8/ All hay, sorghum forage, and for 1940 to date, sorghum silage.

9/ All wheat, rye, buckwheat, and rice.

10/ Potatoes, sweetpotatoes, dry edible beans, dry field peas, truck crops for processing, truck crops for fresh market, and farm gardens.

11/ Fruits, berries, and tree nuts.

12/ Sugar beets, sugarcane for sugar and seed, sugarcane sirup, sorghum sirup, maple sugar, and maple sirup.

13/ Cotton lint and cottonseed.

14/ Soybeans, peanuts picked and threshed, peanuts hogged, flaxseed, and for 1940 to date, tungnuts.

15/ Hay and concentrates only.

16/ Preliminary.

Note: Supplement I to this publication contains a similar table for each geographic division. See Preface.

ACREAGES OF HARVESTED CROPS USED FOR SPECIFIED PURPOSES

This series measures changes in the total acreage of crops harvested, in acreages used for different broad purposes, and in acreages used per capita to produce food, fiber, and tobacco for domestic human use. The acreage for per capita production is derived by subtracting from total harvested crop acres the sum of the acreages used for producing export products and feed for all horses and mules in the United States, and dividing the remainder by the total population of the United States on July 1.

It should be noted that these acreages are for harvested crops only. They do not include acreages of pasture. Total harvested crop acres consist of the area in the 59 crops harvested (excluding duplication) plus acreages in tree fruits, small fruits, tree nuts, and farm gardens. Acreages of several minor crops are not included; in recent years, these minor crops have accounted for about 0.5 million acres. Basic data for the estimates are published in the releases of the Crop Reporting Board of the Agricultural Marketing Service and in Census of Agriculture reports from the Bureau of the Census.

Acreages used for producing exports are determined for each crop exported by dividing the quantity exported by the United States average yield per acre for the given year. There are two steps in computing the acreages of crops used to produce each of the livestock products. The first consists of estimating the quantities of each feed crop used to produce 100 pounds of pork, 100 pounds of milk, 100 dozen eggs, and so on. The second consists of determining the quantity of each feed crop used to produce the products exported, and then determining the acreages needed to produce each feed crop, at United States average yields per acre. Periodic 5-year average yields rather than yields for each year are used.

The method used to convert exports of pork and lard to acreages of grain crops will illustrate the procedure. Pounds of pork exports for a given year were divided by 0.703 to convert the exports to a live weight of hog basis. Exports of lard were divided by 0.562 to determine the live weight of hogs required to produce the lard.

On the average, it was assumed that approximately 400 pounds of grain (corn equivalent) were required to produce 100 pounds of live weight of hogs, in the usual proportion of pork and lard exported. At average 1935-39 corn yields, 1 acre of corn would produce about 340 pounds of hog, or corn from 0.292 of an acre would be required to produce 100 pounds of live hog. 0.292 times the total hundredweight of live hogs from which the exports came gives the total acreage of corn used to produce the pork and lard exported. Similar procedures were used to convert other animal products exported into the crop acreages required to produce them.

From 1910 to 1939, farm acreages used to produce crop exports are based on the average United States yield of each crop exported for the specified year, and the quantity exported during the year, beginning with July or with the month that represents the start of the crop season. Beginning with 1940, acreages for crop exports and lend lease are for calendar years, and, as above, they are based on average United States yields for specified years.

Acreages for producing livestock exports for 1910 to 1939 are based on United States average crop yields for 1935-39, and the volume of livestock products exported during the specified year beginning July 1. Beginning with 1940, livestock for export and lend lease are for calendar years. From 1940 to 1944, acreages used for exports are based on yearly exports and United States average yields for 1940-44; for 1945-49, yearly exports and 1945-49 average yields were used; for 1950-56, yearly exports and 1950-54 average yields were used.

Yield data for making the export estimates are taken from the various reports of the Crop Reporting Board. Data for volume of exports prior to 1940 are from various issues of Agricultural Statistics, issued by the United States Department of Agriculture. From 1940 on, they are summarized from reports and records of the consumption section of the Statistical and Historical Research Branch, Agricultural Marketing Service.

Estimates of feed consumed by horses and mules are based on average rations of corn, oats, and all hay, as follows. From 1910 through 1919, the calculations allow 800 pounds of oats, 1,600 pounds of shelled corn, and 1.8 tons of hay per head for farm horses and mules 3 years or more of age and animal-unit equivalents for younger animals. From 1920 through 1940, it was assumed that as farm horses were worked less, they consumed less grain and more hay per head. Consequently, the rate of feeding corn was decreased 10 pounds per head per year and the rate of feeding hay was increased 20 pounds.

Beginning with 1941, and for some years thereafter, it was assumed that horses and mules would work less each year, and that on the average they would be fed less corn, oats, and hay and would consume more pasture. Estimated reductions in the grain ration were made by 5-year periods extended to 1965, as it was assumed that no further reduction in the grain ration would occur after that year. The reduction varied slightly from year to year and over the entire period, 1940-65, it averaged as follows: Corn, 16 pounds per head per year; oats, about 19 pounds per head per year. The same procedure of estimating was followed for hay, except that no further reduction in the average hay ration was allowed after 1955. The average annual reduction in hay consumed per head from 1940 through 1955 was about 21 pounds.

For nonfarm horses and mules it was assumed that up to 1931 the quantities of grain and hay consumed per head per year were a third more than those consumed by farm work animals. Since then the computations have rounded out to 1 million acres for producing feed for nonfarm horses and mules.

United States average yields of corn, oats, and all hay were used to determine the acreages required to grow the feed consumed by all horses and mules. From 1910 to 1950, average yields for each 5-year period were used to convert quantities of feed to acreages for each of the 5 years. From 1950 through 1956, average yields for the particular year and the previous 4 years were used.

Basic data on horse and mule numbers and average crop yields are from publications of the Crop Reporting Board of the Agricultural Marketing Service. The horse and mule rations are based on data from many sources, especially from a publication of the former Bureau of Agricultural Economics 1/, and on judgment of workers familiar with the subject.

1/ Acreages for producing export products and horse and mule feed include acreages used to produce the seed used to grow the crops exported and the feed used to produce export livestock products and to keep horses and mules.

2/ Area in crops harvested (excluding duplication) plus acreages in fruits, tree nuts, and farm gardens.

3/ Acreages for crop exports from 1910 to 1939 relate to exports for year beginning July 1, or month representing beginning of crop season. Acreages for producing livestock exports from 1910 to 1939 relate to livestock products exported during the specified year, beginning July 1. Acreages for crop exports and lend lease, beginning with 1940, are for calendar years as are livestock exports and lend lease.

4/ Feed computations for farm horses and mules assume decreasing quantities of grain per head since 1920 and decreasing quantities of hay per head since 1940. From 1931 on, the acreage required to feed all nonfarm horses and mules has rounded to 1 million acres.

5/ Includes products used by our military forces in this country and abroad, and by our domestic civilian population.

6/ Includes persons in our military forces in this country and abroad.

7/ Preliminary.

CROPLAND USED FOR CROPS AND CROP PRODUCTION PER ACRE

The series on cropland used for crops is made up of three components - acres of harvested cropland (land from which one or more crops were harvested), crop failure, and summer fallow. Idle cropland is not included, as the series is intended to measure changes in the land area in crops or being prepared for crops the following year. Land in soil-improvement crops during the entire year and not harvested is omitted also.

Reports of the United States Census of Agriculture and the series on principal crops harvested prepared by the Crop Reporting Board of the Agricultural Marketing Service were used in building up the series on harvested cropland. Census reports of harvested cropland were used for census years, and interpolations for intervening years were based on the Agricultural Marketing Service series on principal crops harvested.

Data on acreages of crop failure were developed similarly. Census reports of acreage of crop failure were used for census years, and interpolations for intervening years were based chiefly on differences between planted and harvested acreages of principal crops as estimated by the Agricultural Marketing Service.

Estimates of acreage of summer fallow were made only for the geographic divisions that lie west of the Mississippi River. Since 1944, estimates of fallow have been based on data contained in an annual report of the Great Plains Council, on the 1949 Census of Agriculture, and on data from the 1951 Productive Capacity Study. 2/ Estimates for earlier years were built up from fragmentary data available in the former Bureau of Agricultural Economics.

Index numbers of total crop production were divided by indexes of cropland used for crops to derive indexes of crop production per acre. Indexes of crop production were developed as one step in the calculation of farm output. An explanation of the series on crop production is given elsewhere in this report.

The index of crop production per acre differs from the index of crop yields per acre of 28 crops, prepared by the Crop Reporting Board of the Agricultural Marketing Service. The latter index is computed from yields of 18 field crops per acre harvested and yields

433305 O - 57 - 3

of 10 fruits per acre of bearing age. The yields are combined in proportion to the relative values of the crops during the 1947-49 period. Thus, the crop-yield index uses constant-value weights for each of the 28 crops throughout the period 1910 to date. In contrast, the index of crop production per acre gives a variable weight to individual crops in each year according to the relative production importance (as measured in either 1935-39 or 1947-49 prices) of the crops in that particular year.

The yield index of 28 crops is computed on a basis of harvested or bearing acreage. The index of crop production per acre is computed on the basis of cropland used for crops.

1/ Preliminary.

USE OF FERTILIZER AND LIME IN THE UNITED STATES

Data on consumption of fertilizer for the early years have been compiled from various sources, including State reports and annual estimates made by the National Fertilizer Association. The first fertilizer grade survey made by the Division of Fertilizer Investigations, in the former Bureau of Plant Industry, United States Department of Agriculture, in cooperation with the National Fertilizer Association was for the year ended June 30, 1934. Another joint survey was made 5 years later in the same way. This was followed by a fertilizer consumption report prepared by the Division of Soil and Fertilizer Investigations, in the former Bureau of Plant Industry and Soils, United States Department of Agriculture, for the calendar year 1941. Annual surveys were made by this division and subsequently by the Division of Fertilizer and Agricultural Lime in the former Bureau of Plant Industry, Soils and Agricultural Engineering, United States Department of Agriculture (now Fertilizer and Agricultural Lime Section, Soil and Water Conservation Research Branch, Agricultural Research Service, United States Department of Agriculture) starting with the fiscal year ended June 30, 1943. These surveys are based on questionnaires sent to all manufacturers of fertilizer. In recent years, completed returns have been received from producers of more than 96 percent of all fertilizer used annually. Returns from the questionnaires are studied and correlated with State reports. Adjusted figures account for total use of fertilizer. The quantities of plant nutrients consumed are obtained by multiplying the tonnages of the different grades of separate materials and mixtures consumed in each State by the weighted average composition of the respective grade as obtained from annual State reports. The data are assembled and annual reports of consumption are published (1) in processed form by the United States Department of Agriculture and (2) in the national agricultural journals.

Estimates of use of lime for the continental United States were developed from various sources by the National Agricultural Limestone Institute, Inc.

ANIMAL UNITS OF BREEDING LIVESTOCK AND LIVESTOCK PRODUCTION PER BREEDING UNIT

The index of animal units of breeding livestock is based on numbers of milk cows, beef cows, ewes, hens and pullets, and sows and gilts on January 1, the number of goats clipped, the total number of turkeys on January 1 for 1939 and prior years, and the number of turkey breeder hens on January 1 for 1940 and subsequent years.

Two weight periods were used to combine the numbers of the various types of breeding units into a total. Average contributions of each breeding unit to livestock production in 1935-39 were the weights used for 1939 and prior years. Weights based on contributions to livestock production in 1947-49 were used for the period 1940 to date. The two subperiods were "spliced" together in 1940 by using overlapped calculations for that year.

The weighting system can be illustrated for the 1935-39 weight period. On an average in these years, a milk cow produced, in terms of 1935-39 average prices, about $80 worth of livestock products; a hen or pullet contributed about $2.50. These value weights were applied to numbers of milk cows, and hens and pullets, respectively, in calculating the index of animal units of breeding livestock each year from 1919 to 1939.

An index of livestock production per breeding unit was obtained by dividing an index of livestock production by the index of animal units of breeding livestock. The index of livestock production used was the one derived in the calculation of farm output. An explanation of the latter series is given elsewhere in this report.

FEED PER UNIT OF PRODUCTION

These data are the result of balancing the annual feed disappearance against livestock production, both sets of data being official estimates of the U. S. Department of Agriculture. The allocation of feed as between the different kinds of livestock was made on the basis of farm-management studies of individual farms, feeding experiments at experiment stations, and collateral information. Feed for milk cows has been obtained directly from farmers since 1930. Although much estimating is involved, practically all of the feed fed and most of the livestock in the United States are accounted for. Feed, including grain, hay and pasture, is measured in feed units. A feed unit is the equivalent in feeding value of a pound of corn.

1/ Live-weight production

2/ Much feed was salvaged from waste feed by farm flocks in the early years.

MAN-HOURS OF FARMWORK

The series of man-hours of farm labor measure the labor input in farming. The series were developed for each year by geographic divisions, beginning with 1919, and for the United States, beginning with 1910. They are built up by individual farm enterprises by applying average man-hours per acre of crops and per head or unit of production of livestock to the official estimates of acres and numbers reported by the Crop Reporting Board of the Agricultural Marketing Service.

Time for farm maintenance or general overhead work is calculated separately and added to the direct hours for crops and livestock used in arriving at the total number of man-hours. Estimates of annual man-hours per acre or per head are made by interpolating between or extrapolating from benchmarks.

Benchmarks consist of estimates of labor used per acre and per head in each State converted to a geographic-division basis. These State estimates for 1939, 1944, and 1950 may be found in two reports of the former Bureau of Agricultural Economics and in reports of the former Production Economics Research Branch, now the Farm Economics Research Division, Agricultural Research Service. 3/ Similar benchmarks for 1910, 1919, and 1929 were developed from data in the Works Progress Administration National Research Project reports which were summarized in a report issued by the former Bureau of Agricultural Economics. 4/ These reports were based on extensive field surveys, while the first-mentioned group of studies were based on secondary data such as are reported in State experiment station bulletins and studies of changes in farm practices and mechanization.

The interpolation of man-hours per acre or per animal between benchmarks and extrapolation beyond benchmarks are modified by several factors. For crops, these include such items as yields per acre, utilization of the crop, methods of harvest, and source of power as indicated by numbers of tractors and workstock on farms. For livestock, the modifiers include such factors as size of enterprise, production per animal, such as milk per cow or eggs per hen, and extent of different methods and practices followed, such as use of milking machines.

1/ Preliminary.

FARM LABOR PRODUCTIVITY

Index numbers of farm output and production by groups of enterprises are divided by the appropriate indexes of man-hours of labor input in computing index numbers of production per man-hour.

The indexes of labor productivity reflect the net effect of all factors that affect either farm production or labor input. It would not be correct to attribute all the changes in efficiency to farm labor. Labor is one of the most important inputs in agricultural production, however, and changes in the ratio of production to labor provide a useful measure of changes in efficiency of farm production. But changes in production per man-hour of labor must be interpreted in the light of changes in mechanization, yields of crops and livestock, and the other technological forces that operate on labor input and farm production.

The Bureau of Labor Statistics, United States Department of Labor, also calculates an index of labor productivity in agriculture. But it differs significantly from the series presented in this report. First, the Bureau of Labor Statistics' index is based on production per farm-worker and consequently it is computed for total farm production only. In contrast, the indexes presented in this report are developed for several groups of farm enterprises. Second, the production index used by the Bureau of Labor Statistics is constructed by weighting data on production of farm commodities with estimates of unit man-hour requirements to produce each product in the base period. The Agricultural Research Service uses a production index that is based on constant price weights. There are also differences in coverage between the 2 indexes. A more detailed explanation of the differences between the 2 indexes of production and the 2 labor-productivity series may be found in a report of the Bureau of Labor Statistics. 5/

1/ Preliminary.

NUMBER OF FARM MACHINES

The series on farm machines gives numbers of eight important machines on farms on January 1, or on a date specified. Each series is the number of the specified machine of all types, sizes, and ages. For example, an old automobile of 20 to 30 horsepower is counted as one just as a new automobile of more than 200 horsepower is counted as one; and an old machine that is used very little during the year counts as much in the series as a new machine of the same kind with heavy use.

Because of the varied nature of the machines included in each series, recent changes in numbers have more definite meaning than longtime changes. This is particularly true for tractors and automobiles and perhaps in a lesser degree for motortrucks. Since 1945, tractor numbers have been published for three classes of tractors--wheel, crawler, and garden. In recent years, a larger percentage of combines are of the smaller sizes and of the self-propelled types. More farms with small dairy herds now have milking machines than in earlier years. Modern pickup balers and field forage harvesters may generally be assumed to be more efficient than earlier models.

Numbers of tractors, trucks, and automobiles for 1920, 1930, 1940, 1945, 1950, and 1955, except for tractors for 1940, are figures reported by the Censuses of Agriculture. Preliminary estimates of tractors for noncensus years are made annually and adjusted when the census data become available. Prior to 1950, the number on farms for a given noncensus year was determined by adding to the number at the beginning of the year the number shipped for farm use by manufacturers, and an estimate of the number imported for farm use in that year, and subtracting an allowance for disappearance during the year. After the 1950 census, the chief basis for making the preliminary annual estimates has been the results of a mailed questionnaire to crop correspondents of the Crop Reporting Board, Agricultural Marketing Service, on tractor numbers on their farms.

For noncensus years, an adjustment was made in shipments of garden tractors to allow for those not going to farms. The adjustment assumed that in these years only about a fourth to a third of the shipments of garden tractors reported by the Industry Division, Bureau of the Census, actually go to farms. The rest are bought by nonfarm users. These percentages were determined by relating the total number shipped between 1945 and 1950 to the numbers on farms in these 2 years, as reported by the Census of Agriculture.

Numbers of automobiles and motortrucks for early noncensus years are based on annual registrations for a limited number of agricultural States and a few special sample surveys that were nationwide in scope. Since 1951,

additional data on numbers of automobiles and trucks on farms of crop reporters have been available.

The 1950 Census of Agriculture reports the number of grain combines and cornpickers on farms, and the number of farms having milking machines. The 1945 census contains the same information for combines and milking machines. In 1942, estimates were made of numbers of grain combines, cornpickers, and farms having milking machines from information supplied by crop correspondents. 6/ Estimates of numbers of combines on farms in 1920 and 1930 were made from data on the manufacture and sales of farm equipment, and from correspondence. 7/ These are the basic points from which estimates for dates prior to 1950 were made.

Since 1950, crop correspondents have reported numbers of combines on their farms. The 1910 estimates for combines are based on fragmentary information for California where most of the combines were at that time. For example, "Farm Implement News" estimated 500 to 600 combines in California in 1888. 8/ From 1940 to 1944 inclusive, the estimates are based on numbers shown for 1930, intermediate estimates by Hopkins, 9/ occasional data obtained in special surveys, and domestic sales since then, adjusted to be in line with numbers reported in the 1945 Agricultural Census. For years since 1945, preliminary estimates of combines are based on domestic sales, imports, and information obtained from crop correspondents. These estimates have been adjusted to census numbers shown in 1950 and in November 1954.

Numbers of cornpickers on farms and farms with milking machines have been estimated in a way similar to that used for estimating grain combines. Primary sources of information for these estimates are the estimates for 1942 reported in F.M. 46, domestic sales reported in Facts for Industry reports, 10/ the Agricultural Censuses of 1945, 1950 and November 1954, and data from crop correspondents for cornpickers since 1950, and for milking machines for 1952 and 1953. Early estimates for combines, cornpickers, and milking machines were adjusted from time to time as new data came to light or new studies were made.

9/ Hopkins, John A., and others, Wheat and Oats. U. S. Works Progress Admin., National Research Project, Report No. A-10. April 1939. This report shows 70,000 combines in 1936 and 90,000 in 1939.

10/ U. S. Bureau of the Census. Facts for Industry.

In 1942, estimates were made from information supplied by crop correspondents on number of pickup balers on farms, and in 1950, the Census of Agriculture obtained the number on farms. Intermediate estimates were based largely on annual shipments of manufacturers. Estimates since 1950 are based on shipments and for some years on numbers reported by crop correspondents. Numbers of forage harvesters for 1951 and 1954 are based largely on reports from crop correspondents. For 1952 and 1953, shipments of manufacturers were used in making the estimates.

For both pickup balers and forage harvesters, it was necessary to adjust slightly only the 1955 preliminary estimates when the November 1954 census reports became available.

1/ Facts for Industry reports of the Bureau of the Census, annual registrations of motor vehicles, and results of enumerative surveys were used in developing estimates for years and machines not covered by census reports.

2/ Census of Agriculture, census dates January 1, 1920 and 1945; April 1, 1930, 1940, and 1950.

3/ The Census of Agriculture of 1940 reported 1,567,430 tractors on farms on April 1. The figure used in this series is an adjusted census figure to make allowance for tractors added to the number on farms between January 1 and April 1. Similar adjustments for other census years were not considered worthwhile.

4/ Information for previous years is not available.

5/ Census of Agriculture, November 1954.

6/ Preliminary.

PERSONS SUPPORTED BY PRODUCTION OF ONE FARMWORKER

This series measures the number of consumers who are supported by the agricultural production of one farmworker. Actually, the series is a ratio of consumers to farmworkers in the United States. The ratio varies from year to year, depending on total agricultural production, agricultural imports and exports, total population of the United States, and number of farmworkers. But the longer time changes are a type of measure of farmworker efficiency, expressed in terms of number of persons per worker supplied with food, fiber, and tobacco.

The term, "consumer support," has not meant the same thing over time. In the early part of the 137-year period, farmworkers did many things both on the farm and in the farm home which later were done by city workers. Furthermore, agricultural products supplied consumers probably are now greater than they were in early years when diets and clothing were simple and sometimes meager.

The first step in measuring the number of consumers supplied with their agricultural needs by one farmworker is to determine the level of products available for consumption per capita. The total amount available for consumption in this country during any given year is the current dollar value of farm production in this country minus the value of agricultural exports plus the value of agricultural imports; and this value divided by the total population of the country gives the per capita level of agricultural products available for any given year.

The value of farm production in the United States minus the value of agricultural exports equals the value of agricultural products available to our population from United States production. This value divided by the per capita level of agricultural products available gives the number of persons in the United States who could be supplied at this level of support with agricultural products from our farm production.

The value of agricultural exports divided by the per capita level of agricultural products available in the United States gives the number of persons abroad who could be supplied at the same level with agricultural products from our farm production.

Because of their close interrelationship, the two accompanying series, total farm employment and total United States population, are carried along with the series on persons supported by the production of one farmworker. Employment data for 1820 to 1900 are estimates based largely on the size of the labor force engaged in agricultural pursuits. 11/

11/ U. S. Bureau of the Census. Sixteenth Census of the United States: 1940 series, P-9, No. 11, March 1942.

Data for 1910-56 are taken from releases on farm employment issued by the Agricultural Marketing Service, rounded to the nearest hundred thousand.

The source of the population estimates is the Bureau of the Census. Data are adjusted to 1940 definitions, and those in later years include civilians overseas with the Armed Forces. Figures for 1820 to 1840 are from the "Statistical Abstract," 1943; those for 1850 to 1890 are from the "Statistical Abstract" for 1944-45; those for 1900 to 1953 are from the "Statistical Abstract" for 1954, and those for later dates are compiled from reports of the Bureau of the Census, rounded to hundred thousands. 12/

Data on value of exports for 1820 to 1840 are estimates made from data from several sources; those for 1850 to 1890 are from the Bureau of the Census "Statistical Abstract" for 1944-45; 13/ and those for 1900-56 are based on computations of the Foreign Agricultural Service, published in "Agricultural Statistics." 14/

For the purpose intended, the series serves very well. As a longtime measure, it appraises adequately the changes in efficiency of farmworkers. It is not intended to be a precise index of slight year-to-year variations in worker efficiency. Slight variations from year to year or during short periods merely denote changes caused primarily by ups and downs in total yearly agricultural production and farm employment.
